Date : September 9, 2013

## **Acknowledgements**

I would like to extend my sincere thanks to Dr. Colin Dodds and Dr, Francis Boabang for all their assistance and patience in helping me complete this Master Research Project.

To my friends, Abhinav Bhatnagar and Kuang Liu, I am extremely grateful for their assistance and encouragement.

Finally, I would like to thank my family for supporting my education.

## **Abstract**

Testing for "January Effect" in Canada's Financial Services

by

Jing Li

September 12, 2013

This paper examines existence of January effect in the financial services industry in Canada. A regression model with dummy variables has been used to detect the January effect from 2003 to 2012. The January effect is a trend for stocks, particularly for small-cap firms. There are at least five reasons to explain why this market seasonality might occur, for instance, tax loss selling, the intergenerational transfer hypothesis, CAPM misspecification, seasonal information flows and window dressing.

This paper found a weak January effect in small-cap firms before 2009, and this effect has declined in recent years with a more efficient capital market. While the January effect does not hold for each individual firm, this result cannot confirm the previous studies about the existence of January effect in Canada. Therefore, there are no abnormal returns for investors to take advantage of this January anomaly.

# **Chapter 1**

## **Introduction**

### **1.1 Purpose of the study**

Numerous empirical studies have examined the randomness of stock price movements after Fama developed the Efficient Market Hypothesis (EMH) in 1970. EMH asserts that future stock prices cannot be predicted by using past prices, i.e., over time stock prices change randomly. However, some predictable seasonal patterns, commonly known as seasonal anomalies have been proved to exist for more than half a century. For example, EMH has been tested worldwide by different calendar anomalies, e.g., days of the week effect, month of the year effect, January effect, holiday effect, etc. Anomalies represent inexplicable events, which cannot be adequately explained by existing scientific theories, concepts, or data. Those phenomena help financial institutions or individual investors to generate persistent abnormal return by inefficiencies stock market.

The objective of this paper is to study whether or not the "January effect" exists in the financial services industry in Canada. If it exists, this paper will explore how investors use this information to make abnormal returns during the December-January period.

The January effect documented by Keim (1983), describes the tendency for stock prices to rise during the period beginning with the last trading day in December and ending on the fourth trading day in January. Keim and others also observed that

smaller firms have higher returns than larger firms, on average over long horizons. The reason for this paper focusing on the finance industry is that researchers have examined the January effect across many different industries, but not specifically the finance industry.

## **1.2 Background**

Fields (1931, 1934) was the first to detect stock markets seasonality in the form of weekend and holiday effects, while Wachtel (1942) discovered the January effect. He proceeded to discuss the evidence of a December-to-January seasonal rise in the Dow Jones Industrial Average (DJIA). Since his discovery, a large number of researchers achieved the same results. This effect is not only found in the U.S. stock market, which is the biggest capital markets in the world, but also worldwide from India to South America, Europe to East Asia.

However, after Wachtel (1942), there has been little progress in more than 40 years. While hundreds of academic journal articles have examined stock market seasonality, primarily, these studies have been event-based, and lack a theoretical structure to provide for the orderly examination of these so-called seasonal anomalies. Consequently, research progress in this area has been severely inhibited.

In recent years, researchers developed five explanations for the January effect.

**1.2.1.** Beginning with the most popularly explanation, which is tax loss selling. Investors' usually sell stock securities at year end to realize losses and this can be used to offset capital gains and thereby lower an investor's tax liability.

**1.2.2.** The intergenerational transfer hypothesis (ITH) is another potentially tax-related explanation for the January effect. The ITH advances the position that the January effect is caused by seasonal modal investor taste and preference shifts and changes in investor composition (Gamble 1993).

**1.2.3.** CAPM misspecification is also attributed to the continued existence of the January effect. This explanation focuses on the failure of the single beta measure to capture all informational risk components associated with stocks.

**1.2.4.** Seasonal information flows is an explanation for the January effect deals directly with the speed and quality of information dissemination. Beaver (1968) examined investor reactions to earnings announcement event dates, via volume and price movements of common stocks over weeks. He concluded that earnings announcements contained information that investors reacted to. However, seasonal information flows and the ITH are not mutually exclusive.

**1.2.5.** Window dressing is a form which engaged by both institutional investors and individual taxpayers. The institutional money manager window dresses the client's portfolio to maximize returns or the perception of future prospects for higher returns. The individual taxpayer window dresses his or her gain and loss realizations to minimize their tax liability.

From above explanations, it is apparently that the various stock markets seasonal cannot be viewed in isolation. For example, January seasonal overlaps with end-of-year seasonal effects, and is associated with the Thanksgiving, Christmas and New Year's holidays, that is, the holiday effect. Therefore, when investors sell their existing securities in December and then repurchased in early January, and realize

abnormal returns, the January effect cannot conclusively be isolated to other seasonal factors.

After almost two decades of extensive studies, it is still difficult to adequately explain the January effect. Consequently, there are many arguments about January effect. Aaron (1998) report that because of the anticipation that the market will decline at the end of December, many investors will sell their securities earlier, and then January effect may become the mid-December to mid-January effect. However, Li (2012) showed there is a significant February effect in China's capital market during 2000 to 2012.

In addition, more studies are paying attention to the question about whether the January effect is still alive in the futures markets, Gu (2003) claims that United Kingdom is experiencing a decline in the January effect. Others such as Schiffres(1994) argued that the January effect may come earlier, Riepe (1998) claim the publicity killing the January effect. Although those situations occurs in some specific country, to varying degrees, the January effect remains a statistically significant and measurable phenomenon worldwide as with the holiday effect.

### **1.3 The January effect and market efficiency**

The efficient market hypothesis (EMH) is a widely-known theory, which defined as the price of any tradable security reflects all information, and that any changes in the information are reflected instantaneously in the security's price. In other words, price

always equals intrinsic value and market-beating techniques such as charting or fundamental analysis are essentially a waste of time. Nowadays, evidence suggests that stock prices are reasonably efficient and they respond rapidly to new information and are difficult to predict future price by historical information. Therefore, the January effect continues to be characterized as an anomaly because it suggests a predictable pattern in stock returns, and this violates the EMH.

Depending on the information used to generate returns, there are three forms of market efficiency and each level of market efficiency is nested within the next level of market efficiency. They are weak form market efficiency, Semi-strong form market efficiency and Strong form market efficiency.

In conclusion, as many researchers of the January effect and other seasonal effects have failed to develop their relation to the three levels of EMH, Anthony (1999) argued that seasonal effects are consistent with the weak and semi-strong forms of market efficiency, but are inconsistent with the strong form. Awareness and anticipation of seasonal return patterns by investors may lead to a precautionary or speculative measure in anticipation of the recurrence of a seasonal effect.

## **1.4 The Financial industry and January effect**

In North America, electricity, gas, postal services, airlines and telecommunication services industries have seen less regulation, which has triggered a large wave of international expansion. Therefore, this leaves the financial industry as one of the

most highly regulated industries in Canada. Especially for life and health insurance companies which can also be provincially regulated.

Elkhal (2004) suggested financial companies are subject to much more regulation than firms in the other areas of surplus requirements, valuation of assets, solvency testing, legal reserves, investment activities and pricing policies. For Canada, the supervision of finance companies is shared by the provincial and federal governments. There are three main reasons for this stringent regulation.

1. Initial and continuing capital and surplus requirements
2. Quality and collectability of assets
3. The adequacy of claims and other reserves

One of primary goals is assurance of solvency, so financers can pay debts and claims when they come due.

Some could argue that a possible result of a heavily regulated finance industry is a reduced finance company stock price variance or volatility. This could diminish tax-loss selling pressure for financial company stocks and hence lead to less of a January effect. This is also the reason for a lacuna in the literature on the January effect in the financial services.

There are five chapters in this paper. The rest of this paper is organized as follows: Chapter 2 is literature review related to seasonality and calendar effects, especially the January effect, and it provides a summary results of the past literature. Chapter 3 describes the data and the methodology employed in order to test for January effects in Canada insurance industry. Chapter 4 presents summary statistics and results for

the tests. The last chapter contains conclusions and recommendation of strategies for investors.

## **Chapter 2**

### **Literature Review**

#### **2.1 The Existence of January Effect**

Wachtel (1942) was the first to examine seasonality in the Dow Jones Industrial Average (DJIA) index during 1927 to 1942. His study is based on the three assumptions: (1) stocks whose prices decreased and sell in December to get tax benefit are usually the high-yielding stocks. (2) Institutions and individuals sell stocks at the middle of December to establish tax losses for tax-saving, and such pressures drives security prices below what they should be according to potential earnings. (3) The rise at the year's end is nothing more than a normal reaction from depressed levels.

#### **2.1.1 U.S. Stock Markets**

After Wachtel (1942), several theories have been put forward regarding seasonal anomalies in the stock market. For example Rozeff and Kinney (1976) brought the January effect to the attention of modern finance and they obtained an average return of 3.48% during January and 0.42% during the remaining 11 months of the year on an equal-weighted NYSE index from 1904 to 1974. Dyl (1977), Branch (1977), Keim (1983), Haugen and Jorion (1996), Mehdian and Perry (2002) also confirmed January effect existence in the United States stock markets. Gultekin's (1983) paper

showed international evidence of January effect and results on the January effect became a global issue.

Schwert (2003) reported that during 1980 to 2001, the January effect weakened but that it still existed. Moosa (2007) showed that a significant January effect existed except for the period 1990-2005 when he tested the effect by using monthly average returns of the U.S. stocks for the period of 1970 to 2005. Mehdian and Perry (2002) concluded that the mean of January returns are positive in U.S. stock markets, but they are not statistically significant after the U.S. stock market crash in 1987. Lindley, Liano and Slater (2004) demonstrated that during the period 1962-2000 many years did not have a significant January effect and that some years had a negative January effect.

### **2.1.2 Canada Stock Markets**

While numbers of researchers have reported stock returns in January in the U.S. exceed returns for others months, Berges, et al (1984) document a similar finding for Canadian stocks over the period 1951-1980. Athanassakos& George (1997) reported that for both large and small Canadian stocks, there was found evidence showing a significant January effect returns which is consistent with findings in the U.S.

### **2.1.3 Other Countries Stock Markets**

The January effect has also been detected in many other countries, Japan (Kato & Schallheim 1985), Malaysian (Nassir & Mohammad 1987), U.K. (Mills & Coutts, 1995), Greece (Mills, Siriopoulos, Markellos & Harizanis, 2000), Chile, Greece,

Korea, Taiwan and Turkey (Fountas & Segredakis, 2002), India (Pandey, 2002), Sweden (Hellstrom, 2002), Nepal (Bahadur & Joshi, 2005), Poland, Romania, Hungary and Slovakia (Asteriou & Kovetsos, 2006), Argentina (Rossi, 2007). However, conflicting results are also available. For instance, in Jordon (Maghayereh, 2003), Greece (Flores, 2008), Brazil, Chile and Mexico (Rossi, 2007) it was not detected.

## **2.2 Influencing factors for January Effect**

Several hundred papers have attempted to resolve the anomalous natures of various stock markets seasonally over the past two decades, especially for January effect. There were tax-loss selling, window dressing, increased liquidity in December, and new information effect, etc.

### **2.2.1 Tax-loss selling**

The tax-loss selling hypothesis (Branch, 1977) asserts that in December, i.e., capital gains and losses are recognized for tax purposes when realized at the end of the tax year, investors tend to sell out the stocks held to write-off capital losses. Stock prices go down as a result of this downward trend in market. When the new tax year comes in January, investors start to buy stocks again and this pushes up the stock prices.

### **2.2.1.1 Studies of relationship between the pre-/post- individual Federal income tax system and tax-loss selling**

I can reference five papers that have examined pre-/post- individual income tax periods to determine whether or not the January effect might be related to tax-loss selling. These are Schultz (1985); Pettengil (1986); Jones, Pearce and Wilson (1987); Jones, Lee, and Apenbrink (1991); and Brailsford and Easton (1993). Only Pettengill defined the pre-/post-tax period breakpoint as 1921/1913. The other four studies' breakpoint is 1917/1918. Schultz (1985) was the first one who uses the pre-/post-individual Federal income tax period to research the January effect. He formed portfolios of small, value-weight firms as samples to obtain monthly returns. The sampling techniques he used for the pre-/post-tax historical periods were sufficient to detect the January effect for the contemporary period. However, he failed to detect evidence of abnormally high returns for small firms in the January. The contemporary period was selected as a comparison against the periods examined by Kiem (1983) and Roll (1983).

For Canada, it did not introduce a capital gains tax until 1973 and Berges, McConnell, & Schlarbaum (1984) reported that January returns in Canada exceeded returns for other months of the year before and after this date. Thus, these data do not support the tax-loss selling.

### **2.2.1.2 Studies of relationship between stock market volume and tax-loss selling**

Dyl (1977) reported there was significant evidence of abnormally high volumes for stocks that suffered a price decrease during December for a Bear market and abnormally low volume for stocks that appreciated during December for a Bull market; Bolster, et al(1989) confirmed December volume higher for winners; Slemrod (1982) detected volume levels of the American Stock Exchange, New York Stock Exchange (NYSE) and over-the-counter markets. The capital gains tax cut in TRA78 resulted in higher post-1978 transactions volume. Results were strongest for the NYSE and could not be completely explained by trend growth in transaction volume. Lakonishok & Smidt (1986) found high turnover for losers in December and low turnover for winners in January; Ritter (1988) claimed individuals have below normal buy/sell ratios in late December and individuals have above this ratio in late January. Ferris, Haugen & Makhija (1989) studied persistent evidence of disposition effect for all months of the year, which means it rejected the tax-loss selling consideration. Henderson (1990) investigated that increase in capital gains tax rates did not result in a significant decrease in volume; Dyl & Maberly (1992) reported that January effect results from individual investors and is not due solely to tax loss selling.

### **2.2.1.3 Studies of relationship between stock market prices and tax-loss selling.**

Constantinides (1984) reported in the absence of capital gains, transaction fees or loss treatment or tax regime, the optimal trading strategy is to defer gains indefinitely

and realize losses immediately. So the tax regime is an important factor when investors consider selling securities. Rozeff & Kinney (1976) claimed the highest monthly mean returns appear in January and Branch (1977) reported it is possible to generate modest abnormal returns after commissions. Reinganum (1983) found small capitalization companies contributed more to January tax-loss selling. This is confirmed by Eakins and Sewell (1993) and Johnston and Cox (1996) who argued that small firms with high January returns have low institutional ownership. Burman & Randolph (1994) demonstrated effects of transitory changes greater than that for permanent changes in tax rates by using state income tax rates. In the same year, Clausing and O'Hare (1994) obtained the similar results. Other researchers, such as Givoly and Ovadia (1983), Badrinath and Lewellen (1993), Dalton (1993) and Koogler and Maberly (1994) all are supportive of the tax- loss selling theory.

In conclusion, although some important research questions arise: Why doesn't tax-loss selling completely explain the January effect? Is tax-loss selling a behavior attributable only to individual investors? Tax-loss selling continues to find support as the primary explanation for the January effect.

### **2.2.2 The Intergenerational Transfers Hypothesis (ITH)**

The ITH defined that the January effect is caused by investors' tastes and preference shifts (Gamble 1993). He suggested that ITH provides a possible explanation for the failure of tax-loss selling because ITH can explain the abnormal returns which are not explained by tax-loss selling. Gultekin & Gultekin (1983) examined 17 countries by using Capital International Perspective indices and Agrawal & Tandon (1994)

examined 18 countries by London Financial Times to found evidence of international January effect related to ITH. Jaffe and Westerfield (1985); Berges, McConnell and Schlarbaum (1984); Brown, Keim, Kleidon and Marsh (1983); Reinganum and Shapiro (1987) all studied tax-loss selling as a possible explanation for the January effect. However, none of these studies examined the alternative explanation of ITH.

### **2.2.3 Capital Asset Pricing Model Misspecification**

The joint hypothesis is comprised by the CAPM and the EMH and these two components cannot be separated since market efficiency must be tested jointly with some asset pricing model of equilibrium (Fama, 1991).

#### **2.2.3.1 Evidence of CAPM misspecification**

Scholes and Williams (1977), Dimson (1979) and Roll (1981) reported that the small firm component of the January effect was related to CAPM misspecification because severely biased beta estimates were due to infrequently traded and this is a characteristic associated with small capitalization firms. However, Banz (1981), Reinganum (1981) and Cook & Rozeff (1984) all confirmed that small firms generate higher returns than larger firms, even on a risk-adjusted basis, earnings -to-price ratio effects contributed more than highly correlated size.

Empirical evidence suggests that investors cannot generate abnormal returns consistently from the January effect in small firms after all transaction costs. This is contrary to the Semi-strong level of market efficiency. Dimson (1979) used developed techniques to eliminate the bias in the beta estimates for small firm stocks.

Strebel (1983) proposed incorporating the information which is contained in the analysts' predicts to eliminate the abnormal returns on small or neglected firms. Chan and Chen (1988) failed to find any explanatory power associated with the firm-size proxy by using the logarithm of firm size.

### **2.2.3.2 Studies of the January effect in bond and debt instruments**

Researchers of bond and debt securities have also found strong support for the January seasonal, and have associated this with the tax-loss selling and small firm effects. Schneeweis and Woolridge (1979) examined public utility bonds and 10-year U.S. T-Bonds and found that the January seasonal effect diminished, Smirlock (1985) reported that January effect existed for low-grade corporate bonds and T-Bills; After that, Kleim and Starmbaugh (1986) claimed a January seasonal was identified in returns for low- and high-grade and commercial paper; Chang and Pinegar (1986) also found evidence of the January effect for long-term, lower quality corporate bonds; Ma, Rao & Weinraub (1988) confirmed January seasonal in convertible bonds and the tax-loss selling features unique to the convertible bond market; Jones and Wilson (1989) investigated the January effect existed with both bonds and commercial paper. And they analyzed commercial paper and corporate bonds in 1990 again and found high January inflation did not provide an explanation for the January effect. Other studies also support the January effect existence in U.S. T-Bill (Park and Reiganum 1986), corporate bond returns (Jordan and Jordan 1991), and preferred stocks (Vetter and Wingerder 1996).

## **2.2.4 Seasonal information flows**

The contemporary literature suggests that the January effect is contributed to seasonal information flows and information asymmetries. Seasonal information flows are related to the speed or level of information dissemination, therefore it is associated with weak, semi-strong and strong forms of market efficiency and as well as CAPM misspecification.

### **2.2.4.1 Studies of earnings announcements and stock market reactions to information**

Beaver (1968) examined investor reactions to earning announcements by volume and price movements of stocks over surrounding weeks and found the investors' reactive were dramatic. However he failed to focus on the January effect. In the same year, Brown and Niederhoffer (1968) paid attention to quarterly earnings reports and found the interim reports were superior to annual reports as predictors of earnings, and they suggested the seasonal information flows-based explanation for the January effect.

### **2.2.4.2 The firm size effect**

Lustig and Leinbach (1983) developed CAPM-based cumulative abnormal returns (CARs) to examine the returns for NYSE stocks by month during 1931- 1979 and claimed the abnormal return would disappear if the opportunity cost was included in the stock price. Barron's (1991) investigated how small firms tend to have more growth potential and usually outperformed larger firms. Banz (1981) used

government and corporate bond return data from Ibbotson and Sinquefield (1997), and then found a size effect provided evidence that the CAPM failed. Roll (1981) suggested infrequent trading for small stocks attributed to firm size effect; Reinganum (1982) claimed the bias or improper securities beta estimation were too small to fully explain the firm size effect. Atiase (1985) examined the January effect as a side effect and future research designs requiring control for private information should also control for firm size; and then Bamber (1986) confirmed in the next year about firm size effect is inversely related to trading volume. Elfakhani(1998) also examined the relation among market beta, firm size and average returns for Canadian stocks during 1975-1992, a negative relation between average return and the market capitalization of firms is documented. Others have also found a function of firm size (Freeman 1987; Bhushan 1989) and registered insiders' ownership reporting (Finnerty 1976; Seyhun 1986).

#### **2.2.4.3 Public or private information**

Huth and Maris (1992) found public information produced only statistically significant, not economically significant reactions, and small-cap firm's reactions were restricted to negative comments. Seyhun (1988) detected seasonal patterns of insider activity and didn't find the evidence to support that insider activity can explain the January effect.

### **2.2.5 Window dressing**

Window dressing is another popular explanation for the January effect. Both Dun's (1983) and Jansson (1983) suggested that window dressing just fools hasty investors. Allen and Saunders examined during the period 1978-1986 that 75% had engaged in window dressing. While Lee, et al (1998) reported the January effect was the result of hedging performance, not window dressing after they analyzed mutual fund data from 1976 to 1993.

## **Chapter 3:**

### **Methodology**

#### **3.1 Data sources**

This chapter provides a description of the empirical model and data set. There are 86 public Canada financial companies and 52 of them have been quoted in the market more than 10 years. Those 52 companies are used to investigate the January effect for financial services in Toronto Stock Exchange (TSX) in Canada from 2003 January to 2012 December.

In addition, the data will be distinguished by the size of company. Companies with market capitalizations less than \$2.4 billion are treated as small-cap companies while others are large-cap companies (See Appendix A). This is consistent with previous research to determine whether the market capitalization of the company will affect the strength of the January effect. Data have been compiled using the adjusted closing price of the individual securities from the first trading day of each month. Stocks quotes and the S&P/TSX composite index were provided by [yahoofinance.com](#) and [Bloomberg](#).

The monthly value of index used the similar criteria listed above, i.e. the closing price on the first trading day of each month as quoted on the TSX in Canadian

dollars, as provided by the Globe & Mail. Since numerous researches have provided negative correlation between interest rates and insurance pricing, 1-year Treasury bill (Secondary Market rate) used as a control variable for testing purposes. Monthly observations were obtained by the average aggregation method and obtained from the Board of Governors of the Federal Reserve System.

### 3.2 Model

The model has been constructed to test whether the January effect exists in Canada in the finance industry. Variables that are considered to have effects on a company's stock price are included in this model, and dummy variables also used in order to isolate the January and other months.

The Monthly return of S&P/TSX composite index is calculated as the natural log of [today's Index Value / previous day's Index Value]:

$$R_t = \ln(P_t / P_{t-1}) \quad 3.1$$

where

$R_t$  = Monthly return of S&P/TSX composite index.

$P_t$  = Closing value of S&P/TSX composite index at time t.

$P_{t-1}$  = Closing Value of S&P/TSX composite index at time t-1.

The reasons to choose logarithm returns over general returns are justified both theoretically and empirically. From the theoretically post of view, logarithmic returns

are analytically more tractable when linked together with sub-period returns to form returns over longer intervals. Empirically, logarithmic returns are more likely to be normally distributed which is a prior condition of standard statistical techniques (Strong, 1992).

To test the existence of the January effect, the following basic regression model can be used (Equation 3.2):

$$E [R_i] = \alpha_i + \beta_{1i}X_{1i} + \beta_{2i}X_{2i} + \beta_{3i}X_{3i} + \beta_{4i}X_{4i} + \varepsilon_i \quad 3.2$$

Where

$E [R_i]$  = the expected return for price of insurance stock i

$X_1$  = the S&P/TSX composite index (by month)

$X_2$  = the market to book ratio of stock i

$X_3$  = the T-bill rate (by month)

$X_4$  = dummy variable, 1 for January and 0 for others

$\varepsilon_i$  = error term, assumed to follow the classical linear assumptions

The rationale for the model is the January effect is captured by the dummy variable  $X_4$ . Other control variables included are market to book ratio, T-bill rate and the S&P/TSX composite index. T-test will be employed to test the statistical significance of parameters. If the January effect exists, the coefficient  $\beta_4$  should be statistically significant.

## **Chapter 4**

### **Empirical Results**

#### **Analysis of results**

The objective of this paper is to detect the existence of the January effect existence in the Canada financial sector by firm size. From Equation 3.2, the significance of  $\beta_4$  can determine the January effect. The other four explanatory variables in the model 3.2 are control variables which will affect the return of securities. The paper obtained results by different data categories, and all results showed whether or not the January effect existed in the financial industry.

#### **4.1 Based on total data.**

From Table 4.1, both large-cap and small-cap companies' stock returns are positive and statistically significant to the index return. This means financial companies' stock prices move in the same direction with the S&P/TSX index change. However, only the small-cap firm stock return is significant to market-to-book ratio and T-bill rate.

The market-to-book ratio is always used to identify whether securities are undervalued or overvalued, so this indicated that small-cap firm's stock prices are more sensitive by the change of the market-to-book ratio.

For T-bill rate, small-cap firms are negatively significant to stock returns. When T-bill rates are high, investors transfer more money to the bond market which will obtain higher returns, but the large-cap firms' stock prices are not very affected by the change of the T-bill rate.

The most interesting part in this paper is that the large-cap firms' showed a stronger January effect than small-cap firms during 2003-2012. This is totally different with prior studies. Although the t-statistic for the large-cap is significant, the R-square is less than 5%, so the model is not fit. Most changes of stock prices cannot be explained by this model. Consequently, the results are not supportive of the existence of the January effect.

Table 4.1

\*Significant at the 5% level

## **4.2 Based on year.**

From Table 4.2, small-cap companies didn't show a January effect after 2009, but there was a stronger January effect during 2003-2009 as evidenced by the significant t-value. It's suggests that the January effect has gradually disappeared in recent years.

The declining of the January effect represents a trend toward market efficiency. Many knowledgeable and experienced investors have employed advances in technical analysis and fundamental analysis to make the market more efficient than before.

From Table 4.3, large-cap companies appear only in some years, and this confirmed the results of previous studies of the size firm effect. From the R-square, it's obvious that Equation 3.2 is more suitable for large-cap companies. Many other control variables did not apply to small-cap companies.

#### **4.3 Based on individual companies.**

From Table 4.4 and Table 4.5, the dummy variable of the coefficient of  $\beta_4$  show only one large-cap firm (BNS) and one small-cap firm (HP-U) has a strong January effect during 2003-2012. However, an individual company is not enough to prove an industry performance so this result is not as reliable as the result based on year. In addition, from the R-squares in regression, in Model 3.2 it is more suitable for firms with capitalization over \$10 billion.

### Results for individual Company: Large-Cap

#### 4.4 Test for December effect and February effect in small-cap firms.

Since many researchers suggested that small-cap firms' January effect has become the mid-December to mid-January effect since investors sell their securities earlier, this paper uses the same data set to try to detect a December effect. The paper redefined  $\beta_4$  to capture the December stock returns. But finds for small-cap firms that

only three months' t-statistics are significant; that is for 2011, 2008 and 2006. This provides some evidence of a December effect. (See Table 4.6)

Others have argued that the January effect may be delayed, such as Li (2012) reported that there was a significant February effect in China's capital market during 2000-2012. However this paper also tested whether Canada's financial industry has a February effect. From Table 4.6, in 2009 and 2007, the small-cap firms' t-statistics are significant indicating some evidence of support for the delayed effect.

Table 4.6

Small-Cap Companies (test for December effect and February effect)

## **Chapter 5**

### **Conclusions and recommendations**

#### **5.1 Conclusions**

Since Wachtel (1942) first detect a January effect, a large number of researchers achieved the results of this effect is not only in the U.S, but also worldwide. Although researchers have examined the January effect across many different industries, the financial industry has not been specifically analysed. This is the reason this paper focuses on the financial industry in Canada.

The objective of this paper is to examine the existence of the January effect in the financial industry in Canada over the period 2003 to 2012. The results are not sufficient to confirm the existence of January effect in the small-cap firms. This paper also detects that neither the December effect or February effect exist in the industry.

The findings of this paper are obviously different from the most previous studies. For instance, Dyl (1977), Branch (1977), Reinganum (1983), Keim (1983), Gultekin and Gultekin (1983), Haugen (1996), Mehdian and Perry (2002), without any exception, all confirmed the existence of the January effect in the stock markets. While it is not surprise to obtain the different results because of the varying estimation model, time interval and data sources, this paper has inherent many limitations which are dismissed in Section 5.2.

From the results, abnormal returns do not exist in the period of December to January. Therefore, firstly, investors and fund managers should maintain their equity positions

in financial securities since there are no opportunities to obtain abnormal return. Secondly, a transaction cost may be higher than any benefit obtained from a January effect, and it is not wise to take a speculative position.

A probable cause is that any January effect that may have existed has now declined with a more efficient capital market.

## 5.2 Limitations

There are several limitations inherent to this study, for instance:

Firstly, 52 companies are not sufficient as a sample to detect the January effect as many of the other companies had not been on the market more than 10 years.

Second, the tested period is 10 years, and this may not be long enough since the January effect was first documented at 1942.

In addition, the goodness fit of the regression model is low. There are other factors that will affect the price of stock that are not included in the model as regression variables. Especially for small-cap firms, this model is not suitable enough.

Finally, in this case, the relationship among T-bill rate, stock price, and index return and market-to-book ratio may be not linear; therefore a linear regression model is inappropriate in these situations.

Therefore, those factors could be the reasons to obtain the different results with previous studies in January effect.

Further research can be conducted, such as to choose another time horizon to test whether the January effect existence before 2009. Other research could focus on the insurance industry since this sector is the most regulated in the financial services sector. Lastly, some other possible kinds of calendar effect could be investigated because the January effect always overlaps with other seasonal anomalies.
